

Using Multiple Pore Pressure Prediction Techniques provides a way to mitigate the increased risk inherent in drilling near or below salt.

A photograph of a rocky, layered geological formation, possibly a salt dome, with a white target overlay consisting of concentric circles and a central red dot. A red line extends from the top left of the slide down to this target.

Question

Why Introduce another Method?
*Because velocity-based pore pressure
does not provide an adequate solution.*

Conclusion: Seismic low frequency interval velocities (trend) can be reliable but the high frequency component is not.

Calibration Implications

- 1) Calibration masks lithology-induced error
- 2) Therefore calibration assumes a constant lithologic trend
- 3) So if calibration is in a shaley area and proposed location is sandy the prediction will be wrong
- 4) And still assuming perfect velocities...

What do we need?

- 1) Seismic attribute that is more stable than velocity
- 2) And less sensitive to lithology
- 3) And more sensitive to pore pressure

Reflectivity

In 1938 Birch and Bancroft noted that acoustic attenuation is more sensitive to effective stress than to lithology.
